Theo Overview & Thesis

Slide 1: Theo at a Glance

Slide 2: Where Issuance-Only RWA Models Can Fall Short

Slide 3: Capital Rails Beyond Issuance

Slide 4: Product Stack & Utility Intent

Slide 5: TVL & Capital Deployment

Theo at a Glance

Theo is an RWA market infrastructure. It connects onchain capital to global financial markets through products designed for issuance, liquidity, collateral utility, and composability.

Its core strategy focuses on building deep liquidity, lending utility, and composability around tokenized real-world assets rather than stopping at primary issuance.

The platform currently centers on four specific tokenized assets.

tULTRA wraps the ULTRA money market fund into a single onchain asset.

thBILL packages that Treasury exposure into a yield-bearing basket token.

thGOLD provides yield-bearing gold exposure through lending arrangements with physical gold retailers.

Finally, thUSD acts as a yield-bearing stablecoin powered by a delta-neutral gold carry trade.

tULTRA

Single-asset wrapper around Libeara's ULTRA money market fund.

thBILL

User-facing Treasury primitive built on top of tULTRA.

thGOLD

Yield-bearing gold product, now in capped early access.

thUSD

Yield-bearing stablecoin built on delta-neutral gold carry and reserve assets.

Where Issuance-Only RWA Models Can Fall Short

Theo pre-builds the missing market layer, which is liquidity, leverage, utility, and integrations, rather than waiting for it to emerge organically.

Issuing the token solves access but it does not create a durable onchain market around the asset. The structural gap appears when a token exists but the surrounding rails do not support it, thus limiting its usability.

Issuance Only	Theo's Approach
Tokenized exposure may still depend on primary mint / redeem if secondary liquidity stays thin	Bootstrap liquidity and market making
Yield-bearing wrappers may remain passive holdings if lending and collateral rails are not built around them	Build collateral and lending pathways
Onchain tokens may have limited composability if DEX, money market, and derivatives integrations do not develop	Pursue protocol integrations across venues
Compliant issuance alone does not guarantee broad distribution across chains and venues	Expand crosschain and venue distribution

Capital Rails Beyond Issuance

Theo's thesis is that issuance is the entry point. The token is the container; the value layer is the system that makes it liquid, borrowable, and composable. Liquidity and utility determine whether an RWA becomes a real capital grade.

Product Stack & Utility Intent

Theo's current products are best viewed as an exposure layer sitting on top of a reusable utility layer.

Exposure layer: what assets does the user hold?

- **thBILL**: basket/iToken that packages treasury exposure into a broader yield-bearing primitive.
- **tULTRA**: single-asset treasury wrapper.
- **thGOLD**: yield-bearing gold exposure.
- **thUSD**: yield-bearing stablecoin built on gold carry, hedging, and reserve assets.

Utility layer: what that asset can do once onchain?

- **Liquidity**: Theo supports market making and multi-venue access so products can trade as instruments, not just wrappers.
- **Collateral Utility**: products are built to support borrowing, leverage, and capital efficiency.
- **Protocol Composability**: architecture targets DEXs, money markets, and structured-product venues.
- **Distribution**: assets are designed to move across chains and venues, expanding reach beyond the primary issuance flow.

TVL & Capital Deployment

Theo's TVL is now distributed across several chains, including Solana, rather than concentrated on a single network.

From end-2024 to its late November 2025 peak, TVL grew by roughly 760%, before retracing about 36.4% to around \$140.2M as of April 20, 2026. For now, this remains primarily a thBILL-driven story; as thGOLD and thUSD go live and scale, their adoption will track incremental demand on top of thBILL. thUSD

Genesis Program already filled in the **\$100M** cap.

Most of thBILL is currently sitting in ULTRA money-market exposure, with only a small USDC balance and almost nothing in pending tULTRA.

Section 2

Architecture & Core Mechanisms

Slide 6: High-Level Architecture

Slide 7: Token Lifecycle Model: tTokens & iTokens

Slide 8: Issuance and Redemption Mechanics

Slide 9: Liquidity Design Principles

Slide 10: Lending & Collateral Utility

Slide 11: Composability as Growth Lever

High-Level Architecture

Theo functions as a full-stack issuance + distribution system where offchain settlement is abstracted behind onchain tokens designed for liquidity, lending, and composability.

Layer 1 - Product Issuance (Offchain + legal/operations)	Regulated issuers originate / settle the underlying RWAs. Reliable issuer settlement is the root of NAV integrity.		
Layer 2 - Tokenization + Accounting (Onchain Core)	tTokens: Single product vaults (ERC-4626). Receipt tokens for one underlying RWA. NAV = onchain balance + pendingAssets (accounts for in-flight settlement).		iTokens: Index / basket tokens (ERC-20). Composed of tTokens / iTokens, priced via onchain oracles.
Layer 3 - Utility rails (Distribution + Use Cases)	Liquidity: Direct liquidity bootstrapping / MMs	Lending / Collateral: Venues like Morpho & Euler. Broad composability.	Multi-Chain: OFT mobility (e.g., bridging thBILL via Stargate)
Layer 4 - Operations & Security (Durability)	Backed minting service (Queue / Orchestrator / Watcher) + MPC funds movement.		Onchain Controls: multisig admin, whitelists, plausibility, upgradeability

Token Lifecycle Model: *tTokens* & *iTokens*

Theo separates single-asset vault accounting (**tTokens**) from basket composition (**iTokens**) to keep settlement complexity in control while maximizing DeFi interoperability.

Why Separation Matters

Compliance Boundary: Mint/redeem gating lives at the product token layer; secondary utility scales via standard interfaces.

UX Upgrade: Optimistic minting + *pendingAssets* delivers immediate liquidity while settlement finalizes in the background.

Protocol Durability: Basket composition (iToken) can evolve safely without touching core, single-asset settlement logic (tToken).

Issuance and Redemption Mechanics

Theo's user lifecycle centers on KYC-gated mint/redeem plus market-native holding and utility via standard token rails.

Expected user lifecycle (thBILL as reference product)

- Mint / access: KYC required to mint. User submits mint order (USDC + permit signature) via API; backend queue/orchestrator processes; MPC moves USDC; optimistic mint can deliver tokens immediately.
- Hold / trade / use: thBILL is non-rebasing (value increases as interest accrues) and can be traded on third-party venues. Multi-chain accessibility and bridging documented (Stargate; OFT deployments).
- Exit / redeem: KYC required to redeem; redemption processed instantly, while underlying collateral settles within 4 business days; redemption returns USDC.

Liquidity Design Principles

Theo's liquidity strategy is to make tokenized products behave like real assets in DeFi by ensuring wide venue coverage, usable depth, and stress reliability.

Price Integrity: Shallow liquidity → wider premium/discount to implied NAV → reduced confidence and lower collateral acceptability.

UX: Users choose the cheapest exit path; fragmentation across chains/venues turns "multi-chain" into "multi-spread."

Protocol durability: Confidence flywheel—tight pricing → more integrations → more utility demand → tighter pricing.

How to validate liquidity

Depth & cost: 0.10% / 0.50% / 1% price-impact sizes; spread (bps); slippage vs size.

Price Integrity: deviation to reference price/NAV proxy over time; premium/discount during stress windows.

Reliability: uptime of core venues; liquidity persistence during volatility; bridge throughput/latency.

Distribution: volume and liquidity concentration by venue/chain (avoid single venue fragility).

Lending & Collateral Utility

Once in circulation, thBILL detaches from the issuance layer and acts as a standard, composable DeFi asset. Users have the choice to bridge thBILL across Ethereum, Arbitrum, Base, and HyperEVM, and find strategies on top of the base yield.

Utility Expansion: Native support for collateralization on onchain protocols and exchanges.

Capital Efficiency: Maintain base Treasury-like yield + borrow liquidity against it for:

- Controlled leverage opportunities
- Additional yield strategies (e.g., Pendle PTs, YTs, and LP)
- Liquidity management

Net Effect: Holding becomes working capital.

Utility Flow:

Composability as Growth Lever

Each integration creates new surfaces where the asset becomes default, collateral, or a building block.

Definition: Assets natively composable with onchain protocols (ERC-4626 for tTokens).

Constraints:

- **Technical:** Oracle requirements, permissioning, upgrade patterns.
- **Risk:** Asset legibility (pricing, settlement latency).
- **Product:** User comprehension of mint/redeem rules.

The Growth Loop:

More integrations → more use cases → natural demand → better liquidity.

Section 3

Products Deep Dive

Slide 12: thBILL

Slide 13: thBILL Borrowing Markets Are Small but Busy

Slide 14: tULTRA

Slide 15: thGOLD

Slide 16: thUSD

Slide 17: Competitive Set by Product

thBILL

thBILL is Theo's user-facing treasury primitive: a tokenized, short-duration US treasury exposure wrapper designed to keep treasury-linked yield usable across onchain markets.

User outcome & promise	Composition	Constraints
Target outcome. Let users park idle USD/stablecoin capital in institutional Treasury exposure while keeping the position transferable, bridgeable, and usable in DeFi; yield accrues through price/NAV appreciation rather than rebasing. Product promise. Theo markets thBILL as AAA-rated Treasury exposure with 24/7 liquidity, instant settlement, and onchain utility.	thBILL is an iToken basket. At launch, that basket holds only tULTRA.  <pre> graph LR USDC[USDC] --> KYC[KYC Mint Flow] KYC --> thBILL[thBILL] thBILL --> tULTRA[tULTRA] tULTRA --> ULTRA_Fund[ULTRA Fund] ULTRA_Fund --> Treasuries[Ultra-short Treasuries / repos / cash] </pre>	• Direct mint/redeem is KYC-gated. • Redemption returns USDC, not the underlying fund unit. • Holders have no claim on underlying assets. • Underlying collateral settlement can take up to four business days.

thBILL Borrowing Markets Are Small but Busy

Tracked external utility remains a minority of thBILL TVL, but the live collateral markets that do exist are heavily used.

Tracked external utility exists in practice, but it remains a minority of native thBILL TVL. The ratio was much higher during the early expansion phase, then fell as native supply grew faster than tracked external reuse. Issuance has scaled faster than publicly visible secondary usage.

Source: DefiLlama, Morpho

Data as of: April 20-22, 2026 - External utility ratio is a public-market proxy. The borrowing snapshot is Morpho-only and does not capture all thBILL usage.

The live thBILL borrowing rails that exist today are relatively small in terms of amount, but they are busy. On Morpho, markets show about \$5.35M borrowed against \$5.91M supplied, with weighted utilization ~90.6%. thBILL already functions as collateral in real markets, despite narrow footprint.

tULTRA

tULTRA is Theo's single-issuer Treasury wrapper, while thBILL is the basket wrapper built on top of it and intended to broaden Treasury exposure over time.

Product Position

thBILL is effectively a one-leaf index today; the economic difference vs. tULTRA is small, but the architectural difference is large.

thBILL is the basket-format product. tULTRA is the direct wrapper around the ULTRA fund.

Facts

ULTRA is a MAS-regulated Singapore unit trust with exposure to ultra-short U.S. Treasuries, repos, and cash reserves. Estimated return is U.S. interest rate less fees.

tULTRA is backed 1:1 by ULTRA shares or USDC reserved to mint ULTRA shares.

thGOLD

thGOLD turns Theo from a treasury-only issuer into a cross-asset tokenization platform by pairing gold exposure with a credit-driven yield engine.

Definition & Utility

It tracks the MG999 Onchain Gold Fund. Delivers spot gold exposure plus 1-2% annual yield via retail gold lending initially to Mustafa Gold. While thBILL acts as base collateral, thGOLD provides directional commodity beta with modest carry.

Access is currently early, capped, and whitelisted.

Expansion & Proof

thGOLD tests if the beyond-issuance stack can support alternative commodity rails.

Important Mechanism Nuance

Unlike thBILL/tULTRA's custom iToken/tToken stack, thGOLD utilizes an operator-controlled ERC-20 with a USDC-based minting contract and whitelist/KYC checks. This places operator controls and offchain underwriting at the absolute center of product credibility.

thUSD

thUSD is Theo's yield-bearing stablecoin powered by gold. It combines long thGOLD exposure with short gold futures and a reserve sleeve, so yield comes from market structure rather than simple Treasury pass-through.

How it works

When thUSD is minted, collateral goes long thGOLD & hedges that gold exposure by shorting gold futures across multiple exchanges, including CME.

Value proposition

thUSD's pitch is that gold gives Theo access to a larger and deeper derivatives market than crypto-native collateral while thGOLD adds a separate lending-yield stream underneath the hedge. That combination aims to produce a stablecoin with high capacity, broader yield base, and less dependence on crypto volatility.

Competitive Set by Product

Theo's multi-product stack spans three distinct product categories.

	Closest alternatives	Same user job	Where Theo differs	Where incumbents are stronger
thBILL  Live	BUIDL, USYC, OUSG, USTB, BENJI, JTRSY	Onchain access to short-duration dollar / Treasury exposure.	Designed as a basket model rather than a direct institutional token wrapper, with a primary focus on post-issuance utility across external trading, lending, and bridging venues.	Smaller scale, weaker issuer recognition, less proven than the biggest Treasury incumbents
thGOLD  Early / Beta	PAXG, XAUT	Tokenized gold exposure in a transferable onchain form.	Attempts to offer productive, yield-bearing gold designed as a composable collateral primitive, rather than simple passive custody.	Less liquid and harder to underwrite than simple gold wrappers like PAXG and XAUT
thUSD  Genesis Program	USDe / sUSDe, USDtb, USX	Onchain dollar for savings, collateral, or treasury use.	Utilizes a unique gold-carry-plus-reserve design rather than relying solely on crypto basis or pure Treasury backing.	Still early live track record against much more established yield-dollar products

Section 4

User Flows & Ecosystem Motion

Slide 18: User Journey: From Access to Utility

Slide 19: Institutional Allocator Flow

User Journey: From Access to Utility

Using **thBILL** as reference, the user journey is a ladder. Access, acquisition, mobility, monitoring, and utility. The model benefits when holders cross from simple exposure into repeated composable use while retaining the initial exposure.

Lane A - Novice / Simple Exposure

Lowest-friction live path today.

Lane B - Advanced / Composable Usage

Institutional Allocator Flow

Before allocating and getting exposure to thBILL a quick diligence procedure can clear any ambiguities: asset underwriting, compliance, operations, liquidity, and monitoring.

How Theo addresses allocator requirements

- Asset confidence: regulated underlying stack with transparent counterparties
- Compliance confidence: gated primary access and whitelist controls
- Operational clarity: published addresses, audits, multisigs, MPC, and defined settlement timing
- Liquidity confidence: present, but still needs deeper depth validation

Section 5

Investment Cases

Slide 20: Bull Case

Slide 21: Bear Case

Bull Case

We believe that Theo's success will depend on whether it works as more than just a wrapper around safe assets. As the protocol itself suggests, the upside lies beyond issuance. The upside is in making thBILL, thUSD, and thGOLD usable across crypto more than competing products. Theo must meet investors and users in the venues that win distribution and mindshare, and activity remains high.

thBILL is the strongest real proof so far in terms of traction and scale because it has been in the market the longest. Tracked external utility was ~6.35% of native thBILL TVL in April 2026. That number is not high and has declined substantially from early last year, when it averaged around 20 to 25%. Still, it shows that thBILL is already being used in lending markets, Pendle, and DEX liquidity rather than sitting only within Theo. Deepening that onchain footprint is key to validating Theo's "beyond issuance" thesis. thUSD

Ondo and OpenEden offer Treasury exposure through both similar and differentiated distribution channels. Theo becomes more valuable only if thBILL is easier to trade, borrow against, bridge, and integrate into strategies than rival Treasury products. If users and protocols begin treating thBILL as working collateral rather than just a yield token, Theo starts to control a more valuable part of the stack. As integrations deepen, thBILL can move closer to becoming a core primitive in onchain finance.

The same logic applies to thGOLD and thUSD. Gold exposure already has strong incumbents in PAXG (Paxos) and XAUT (Tether). Yield-bearing dollars already have incumbents in Ethena's USDe, sUSDe, and OpenEden's USDO. Theo's bet is that productive gold can support a better and more stable dollar product, and that one product can help distribute the next.

thUSD is the latest addition. Theo's public genesis page showed that the \$100M capacity was filled in April 2026. If that converts into sticky thUSD supply, real trading depth, and meaningful collateral usage, then Theo has demonstrated demand for the broader system rather than just the Treasury product. A key question is how deep thUSD integrations go. thBILL already has integrations with Pendle and Morpho. thUSD on Pendle, for example, could become a strong growth driver once live.

We see the core bull case as Theo tying together a usage "ladder" across three investor-favorite categories: users onboard via thBILL, layer in thGOLD, and ultimately adopt thUSD for savings, trading, or collateral. One platform that gives exposure to three core financial primitives, forming a reinforcing product set that deepens adoption among onchain investors who prefer established yield.

Bear Case

The bear case may seem stretched, but ultimately comes down to execution. It centers on thBILL as the only product that really works, while the rest of the platform stack never finds that traction and scale.

The current thBILL data supports that risk. From Theo's API we saw ~\$134.75M of TVL on April 2026, but tracked external utility was around 6.35% of native TVL. It indicates that most thBILL is still being held for yield passively and not used as core collateral or core trading inventory, circulating onchain. The product has traction. The broader market layer is still limited.

Competition is also a concern. Ondo and OpenEden already offer credible Treasury products. PAXG and XAUT already offer simple gold exposure and some onchain utility. USDe, sUSDS, and USDO already offer yield-bearing dollars with deeper liquidity and an established holder base. Theo is entering all three categories against powerhouses and distribution owners.

We could say that this matters most for thGOLD. PAXG and XAUT are easy to understand. Theo adds lending yield through gold-credit relationships. That may improve returns, but it also changes the risk element. An investor looking for gold exposure may not want credit and underwriting risk layered into the product. Investors may also prefer a company like Tether or Paxos with direct physical gold backing.

thUSD has the same issue. A full genesis vault is not the same as real adoption and traction. We raise the question of whether thUSD becomes a real savings asset, a real trading pair, or real collateral after launch. Can it pull an Ethena (USDe)? Even half of Ethena's success in this case can prove to be substantial for Theo. But again, it comes down to execution and of course market conditions.

The weak outcome is not a collapse. We don't expect anything of the sort. The weak outcome is stagnation. thBILL remains a solid Treasury wrapper, while thGOLD stays niche and thUSD stays early, both fighting for market share among giants. Each new product still needs fresh incentives, fresh market makers, and fresh education. In that outcome, Theo has useful products, but not a platform that compounds and scales closer to market leaders.
