With Zero, ZRO is becoming the single asset capable of turning today's institutional supply absorption into a levered bet on the "world-computer" thesis. Now is the time to position ahead of the opportunity, right before Zero, LayerZero, and Stargate economic cash flows fully reprice.

From interop and crosschain infra to extending its capabilities with Zero, their new L1, LayerZero is now pitched as a multi-core world computer that uses ZK proofs to separate execution from verification and scale horizontally via protocol-owned "Atomicity Zones." Zero will not issue a new token; ZRO captures all economic value from Zero, LayerZero, and Stargate. One token, many cash flows.

ZRO is the canonical and only asset of Zero (and LayerZero/Stargate), used for staking and gas. In addition to its current revenue streams (via revenue-funded buybacks) from crosschain swaps, it will start capturing all excess priority and MEV/tips fees from Zero, as well as all trading and payment fees from the markets and payments zones, and, once the fee switch is enabled, a share of every LayerZero message fee.

ZRO Revenue Streams

Pipe	What drives it	Mechanism	What accrues to ZRO
Stargate revenue buybacks	Stargate protocol revenue	Foundation buys ZRO on market	Float reduction (value depends on whether repurchased ZRO is held vs recycled)
LayerZero fee switch (optional)	Messages x fee/message	Fees converted to ZRO and burned	Permanent supply burn
Zero chain fees	Zero tx volume x avg fee	Gas/priority/zone fees (design TBD)	Likely fee-to-stakers and/or burn (model with a capture rate)
Staking demand	Security + governance participation	ZRO staked/delegated	Liquidity sink (supports price via reduced float; not direct cashflow unless fees distributed)

Institutions and LayerZero have already absorbed 19.77% of supply, mainly by buying out upcoming unlocks (meaning public dashboards almost double-count future selling pressure). Besides, Zero's partner slide looks like a wish list: Citadel, DTCC, ICE, ARK, Google, Tether, blue-chip VCs. It's a clear bid for those

looking to own assets that sit at the intersection of institutional trading, settlement, and tokenized assets.

Zero is building open, permissionless infrastructure, targeting mainnet launch this fall. The mental model: one blockchain that runs many “apps” in parallel, like a modern multi-core CPU. Each “core” is an Atomicity Zone: a protocol-owned execution environment that inherits security from the settlement layer. Unlike standard chains, validators don’t re-execute everything. Instead, they verify succinct proofs. That’s how they can claim a scaling roadmap of ~2M TPS per Zone, by removing four bottlenecks with: QMDB (state storage), FAFO (parallel scheduling), Jolt Pro (ZK proving), SVID (data/networking).

Mechanically, execution happens in Zones, proofs get generated by Block Producers, and settlement-layer validators verify proofs. The system supports two validator classes: lightweight validators (low hardware) and optional higher-performance producers.

Interop remains the distribution layer (assets + apps across many chains), and Zero becomes the execution layer for high-throughput markets/payments/other Zones, positioned as a decentralized alternative to cloud providers. Instead of only taxing “messages,” they want to tax economic activity that lives inside Zones (markets, payments, MEV/priority fees), and settle it in one asset (ZRO).
